TFTP (Trivial File Transfer Protocol) is a simple protocol for transferring files across a network. Unlike other protocols, it does not use a central server. It works by sending a request from a computer to another, which then downloads the file and tells the computer how to get more files. The computer then send the request to a further computer which provides the requested file and sends information on further files. There is also a reverse process. This is how a network works. TFTP has a maximum bandwidth of 500 bytes per second per file and an overall maximum of 2,000 bytes per second. A single user can transfer up to 4,500 bytes per second; however, it's not recommended to use over 4,500 bytes per second for each user. TFTP is easy to implement because it does not require special servers like FTP and HTTP servers. Also, it does not require a specific level of permissions like a Windows file share. It's easy to use because it runs on top of any network. It is not specific to any Internet service provider or carrier.
