Evaluation of the effectiveness of prophylactic carbapenem therapy on infectious complications in a cohort of burn patients. Bacterial infection is an independent risk factor for mortality in burn injury. Prophylactic antibiotic therapy is the cornerstone of the management of burn injury.

Carbapenem prophylaxis is preferred. A retrospective cohort study was conducted to assess the effectiveness of

carbapenem prophylaxis in reducing infectious complications. In the period from December 2009 to December 2012, a total of 90 burn patients (male : female = 1:1.1) at the Burn Centre of the Mahavir Hospital, Jodhpur, India were randomly selected for carbapenem and non-carbapenem prophylaxis groups. Primary outcome was frequency of infection. Secondary outcomes were episodes of infection, incidences of colonization and mortality. Baseline demographic data were comparable in both the groups. The infection incidence was 6.2% (2/33) in the carbapenem group and 21.2% (7/33) in the non-carbapenem

group. The difference was statistically significant (p-value = 0.03). The incidence of colonization in the two groups was similar. Mortality was
